

# SIGMA: SIGN-and-MAC

## Crypto rationale and proposals

Presentation by Sara Bitan and Hugo Krawczyk

[sarab@cs.technion.ac.il](mailto:sarab@cs.technion.ac.il)   [hugo@ee.technion.ac.il](mailto:hugo@ee.technion.ac.il)

IETF meeting, December 2001

## Agenda

- Crypto background: key exchange
- The SIGMA approach
- Specific proposals
- Comparison
- MAC, encryption and ESP issues

## Crypto Focus

- Focus on cryptographic design:
  - security: secrecy and authentication (and the subtleties of identity-key binding)
  - sound analysis(proponent's responsibility)
  - PFS: full, windowed
  - identity protection: who, active vs. passive
  - performance: computation, latency
  - DoS protection: adaptive, built-in
- A lot of other issues are essential for a working protocol but **orthogonal** to the above:
  - message formats
  - general mechanisms (e.g., retransmissions)
  - extent of negotiation
  - code preservation vs. “start from scratch”

## Building Authenticated Diffie-Hellman

The basic:

- assumes authenticated channels
- what if man-in-the-middle?

## Attempt at Authenticated Diffie-Hellman

- what if attacker ever finds a triple  $(x, g^x, \text{SIG}_A(g^x))$  ?
  - e.g., file of pre-computed  $(x, g^x)$  pairs
- ephemeral leakage should never allow long-term impersonation

## Authenticated DH (with replay protection)

Note: nonces/cookies omitted (needed if  $g^x, g^y$  re-used)

**A:** “Shared  $K = g^{xy}$  with  $B$ ” ( $K \equiv B$ )

**B:** “Shared  $K = g^{xy}$  with  $A$ ” ( $K \equiv A$ )

Looks fine, but...

## DVW attack [DVW]

- any damage? wrong identity binding!

$A$ : “Shared  $K = g^{xy}$  with  $B$ ” ( $K \equiv B$ )

$B$ : “Shared  $K = g^{xy}$  with  $E$ ” ( $K \equiv E$ )

$E$ : doesn’t know  $K$  but  $B$  will consider anything sent by  $A$  as coming from  $E$

$\{ \text{“deposit attached e-cash to my account”} \}_K$

## Authenticated DH (ISO)

Thwarts DVW attack:

**But is it secure?** Yes: [CK - Eurocrypt'01]

## Identity Protection: from ISO to SIGMA

- ISO protocol: requires peer's id under signature
  - can only protect id's against *passive* attacks
  - active protection possible for one peer at the expense of extra signature and identity disclosure (or added round trips). E.g. JFK.
- Solution: do not bind peer's identity to sig
  - STS protocol (but attacks are possible)
  - two other variants (mac-ed signature and signed-key) are insecure
- Provable secure and efficient:  
**SIGN-and-MAC (SIGMA)**  
[Kra'95]: proposed to Photuris, adopted in IKE

## SIGMA: the basic protocol

Equivalent security (just MAC space saving):

$K_a$  derived from  $g^{xy}$ ; can encrypt with  $K_e$

Note:  $\text{MAC} \equiv \text{prf}$  in IKE

## SIGMA: Basic Design Facts

- **The essential step:**  
**MAC your own IDentity!**
- If ID not inside MAC security is totally compromised (even if ID included in signature!)
- Signature and MAC have complementary and essential security functionalities against M-i-t-M
  - signature protects secrecy of key against exponent replacement by MitM
  - MAC protects identity-key binding against DVW-type attacks by MitM
- ID protection via encryption (resistant to active attacks); but **core authentication security decoupled from ID protection!**
- Flexibility: a lot of possible design trade-offs (see next)

## SIGMA: secure and flexible

next two messages interchangeable!

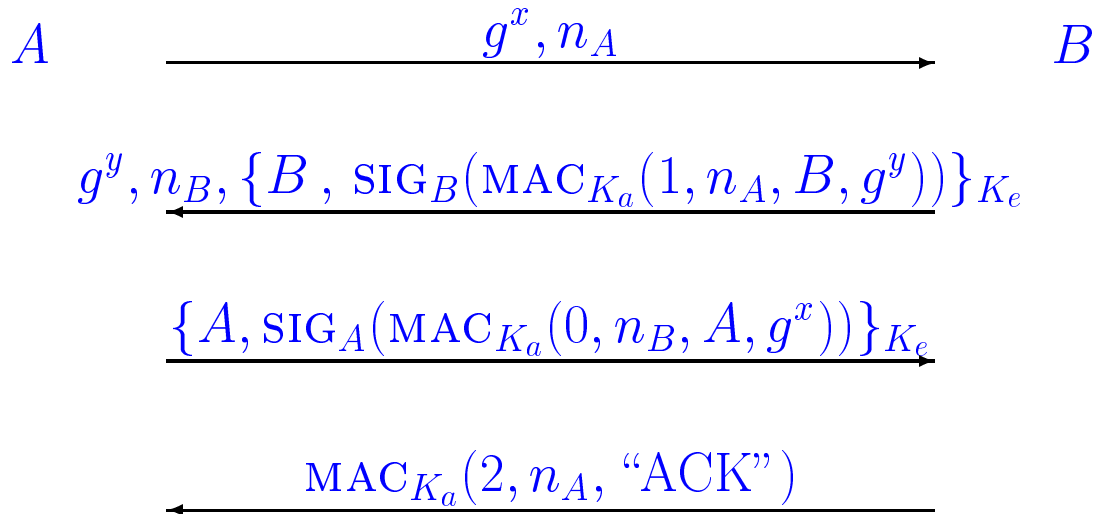

- interchangeability  $\Rightarrow$  design tradeoffs!
  - id protection (active, passive)
  - round trips, computation latency
  - DoS protection (adaptive or built-in)

## Properties of all SIGMA proposals

- Provable secure
- Full PFS (but allow reuse of DH exponents)
- One identity secure against active attackers, one against passive (best possible)
- Best performance for PFS (1 sig, 1 ver, 1 DH)
- Two round trips for core protocol:
  - SIGMA-4 includes DoS protection (in 2 RT)
  - SIGMA-I and SIGMA-R require optional round trip for adaptive DoS protection
- Note: following descriptions place MAC inside signature; MAC outside is equally good IF it explicitly covers identity!

## Specific SIGMA proposals: SIGMA-I

(SIGMA instantiation in draft-sigma; added ack)

- 2 RTs in normal operation
- extra RT if DoS protection activated
- I's id protected against active attacks,  
R's id against passive

## SIGMA-I: IKE-like notation

```
HDR, SA, KE, Ni    -->
                    HDR, SA, KE, Nr,
                    <--  IDir*, [CERT*,] SIG_R*
HDR, IDii*,
  [CERT*,] SIG_I*   -->
                    <--  HDR, "ACK", HASH-ACK
```

Notation:

\*: encryption against active attacks

SIG\_I = signature of I on HASH\_I

SIG\_R = signature of R on HASH\_R

HASH\_I = prf(SKEYID, 0 | Nr | IDii\_b | MSG\_I)

HASH\_R = prf(SKEYID, 1 | Ni | IDir\_b | MSG\_R)

MSG\_I = all information sent by I (except SIG)

MSG\_R = all information sent by R (except SIG)

HASH-ACK = prf(SKEYID, 2 | Nr | HDR | "ACK")

## Specific SIGMA proposals: SIGMA-R

(IKEv2-like but explicit MAC and provable security)

- 2 RTs in normal operation
- extra RT if DoS protection activated
- R's id protected against active attacks,  
I's id against passive

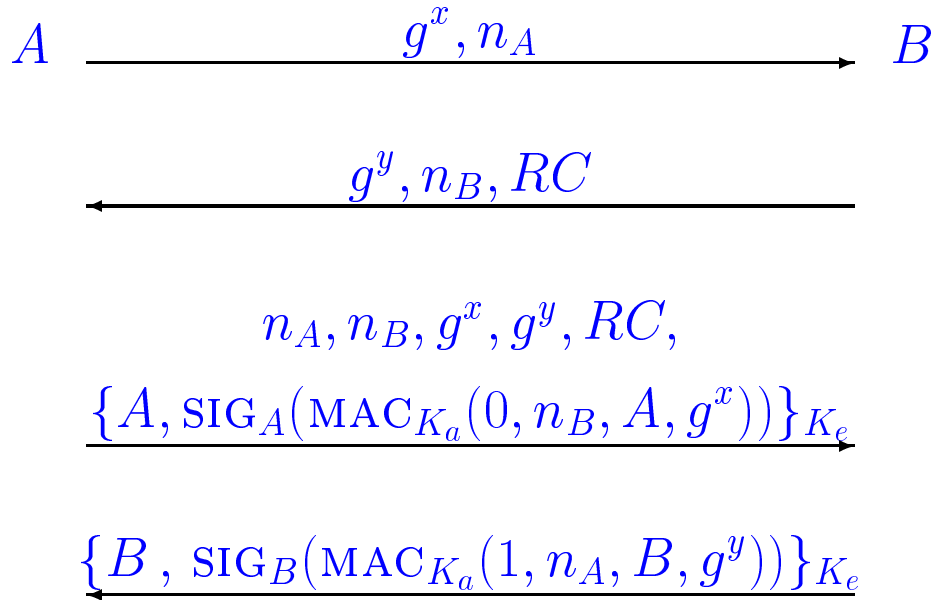

## SIGMA-R: IKE-like notation

```
HDR, SA, KE, Ni  -->
                  <-- HDR, SA, KE, Nr
HDR, IDii*,
  [CERT*,] SIG_I* -->
                  <-- HDR, IDir*, [CERT*,] SIG_R*
```

## Specific SIGMA proposals: SIGMA-4

(A sig-based version of P-SIGMA in draft-sigma:  
a “resolution” of SIGMA, IKEv2 and JFK)

- 2 RTs, including DoS protection via a cookie  $RC$  computed on  $n_B, n_A, g^y$
- R's id protected against active attacks,  
I's id against passive
- long msg3, long input to cookie

## SIGMA-4: JFK/IKE notation

JFK-like notation:

```
I->R: Ni, g^i
R->I: Ni, Nr, g^r, GRPINFOr, RC
I->R: Ni, Nr, g^i, g^r, RC
      E{Ke}(IDi, sa, SIG{i}(MAC{Ka}(0,info-I)))
R->I: E{Ke}(IDr, sa', SIG{r}(MAC{Ka}(1,info-R)))
```

```
RC=Cookie-function(Ni,Nr,g^r)
info-I = Nr, Ni, IDi, g^i, g^r, sa
info-R = Ni, Nr, IDr, g^r, g^i, sa'
```

IKE-like notation:

```
HDR, KEi, SAi, Ni      -->
                        <-- HDR, KEr, SAr, Nr, RC
HDR, RC, KEr, SAr, Nr,
KEi, Ni, IDii*, SIG_I* -->
                        <--      HDR, IDir*, SIG_R*
```

```
With RC=Cookie-function(Ni, Nr, KEr, SAr)
Traffic SA and [CERT*,] payloads omitted
```

## Comparison

Measures:

Security/analysis

DoS: adaptive, built in, cookie gen/ver cost

Id prot: I/R active/passive, transferable proof

Performance (computation)

Round trips

	SIGMA-I	SIGMA-R	SIGMA-4	JFK
		(IKEv2')		
-----	-----	-----	-----	-----
Sec	proof	proof	proof	proof [1]
IDi	active	passive	passive	active[2]
IDr	passive	active	active	none
DoS	adaptive	adaptive	built-in	built-in
Perf	min-PFS	min-PFS	min-PFS	+1 sig/ver
	shrt-cky	shrt-cky	long-cky	long-cky
RTs	2(3)	2(3)	2	2

[1] but high cost: decreased pfs, weak privacy

(R's id revealed + proof of comm), performance-

[2] lost if  $(r, \text{SIG}(g^r))$  ever exposed

## Dual use of MAC

- Two functionalities for MAC
  1. core authentication security of the protocol (identity-key binding) – see Slide 9
  2. identity protection against active attackers (requires integrity mechanism on top of encryption)
- Cleaner and robust: separate the two MAC's:
  - basic principle: keep core authentication independent of id protection
  - example: what if ID not included under encryption, or under a MAC-ed message?
  - use ESP for id protection (save re-specifying ENC modes and algorithms)
  - separation also allows for non-MAC-based ESP specs [Jut01]
- What is the cost of separation? A one-block SHA-1 computation!

## A summary of MAC options

1.  $\text{ENC}\{\text{Ke}\}(\dots, \text{ID}, \text{SIG}, \dots), \text{MAC}\{\text{Ka}\}(\text{ciphertext})$   
secure ONLY if ID is under ciphertext
2.  $\text{ENC}\{\text{Ke}\}(\dots, \text{SIG}, \dots), \text{MAC}\{\text{Ka}\}(\text{ID}, \text{ciphertext})$   
explicit inclusion of essential ID under MAC;  
does not depend on ID position in the protocol  
(e.g. if sent in the clear in the first message)
3. Two MACs (with clearly differentiated goals):
  - one for essential protocol security:  $\text{MAC}\{\text{Ka}\}(\text{ID})$   
(or included under SIG as in current IKE:  
 $\text{SIG}(\text{MAC}\{\text{Ka}\}(\text{ID}, \text{other-signed-info}))$ )
  - another for ciphertext protection only:  
 $\text{MAC}\{\text{Ka}\}(\text{ciphertext})$  (as in item 1)  
(allows use of any confidentiality+integrity  
protecting ESP transform)

Cost of additional MAC: a one-block SHA-1 computation

## “Exercise”: rationale for IKEv2

### Stage 1: exchange DH and SA negotiation

```
HDR, SA, KE, Ni    -->
                   <-- HDR, SA, KE, Nr
```

### Stage 2: authenticate DH exchange and SAs

```
HDR, IDi, SIG(msg1,msg2)    -->
                           <-- HDR, IDr, SIG(msg1,msg2)
```

Identity protection omitted (since core exchange authentication does not depend on it)

### Stage 3: derive keys ( $K_a$ ) from $g^{ir}$ and use them to protect ipsec transform negotiation

```
HDR*, SA, TSi, TSr    -->
                       <-- HDR*, SA, TSi, TSr
```

## Rationale flaw and solution

Above rationale is flawed:

- 3-stage protocol is **insecure** (why? hint: DVW)
- security is “miraculously” saved by the piggy-backing of stage 2 on stage 3 (hint: SIGMA)

**Lesson:** Define exact inputs to SIG and MAC (explicitly ensure essential elements)

**Recommendation:** Make explicit that ID goes under the MAC (regardless of ID’s position in the protocol); sign everything you send and the other party’s nonce.

## Pre-Shared Secret Key

Based on **any** of the SIGMA variants:

- just do not use the signature (but MAC only)
- How to identify the shared key without revealing I's id:
  - (i) point to the shared key via a key-id (static or dynamic) passed in first message, or
  - (ii) derive  $K_e$  directly from  $g^{xy}$ 
    - option (i) gives active protection to I and R,  
option (ii) gives passive to I
- superior defense against DH cryptanalysis
- shares all protocol mechanisms with sig mode! (adds minimal complexity)
- intended for use with strong keys (machine generated and stored); many applications...
