IPsec Architectures

IPsec [RFC4301] described an architecture

- End-to-End Security

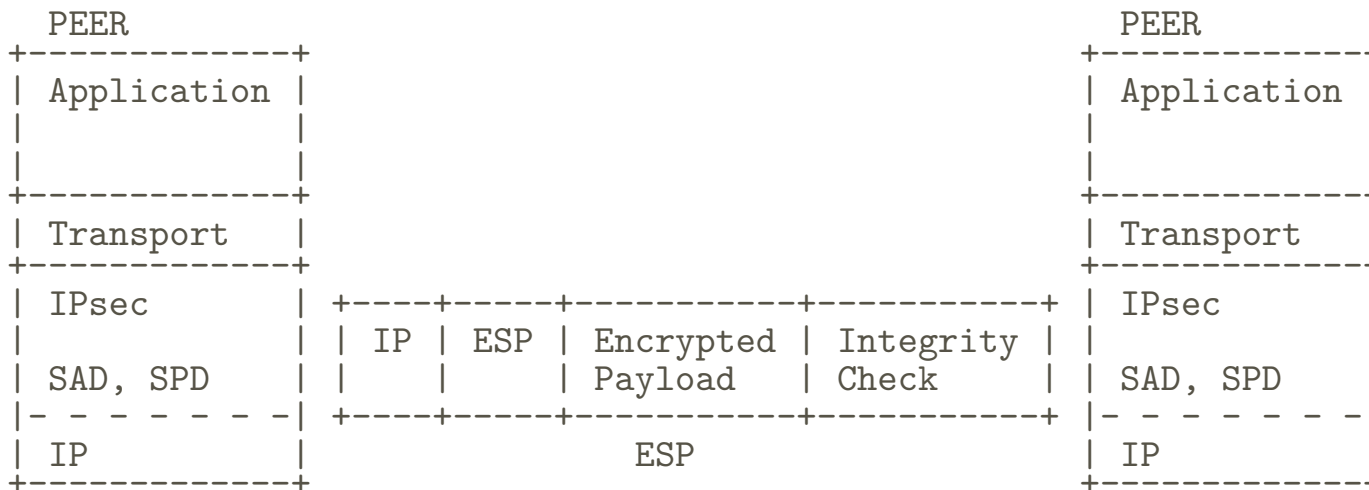

- Virtual Private Network Security (VPN)

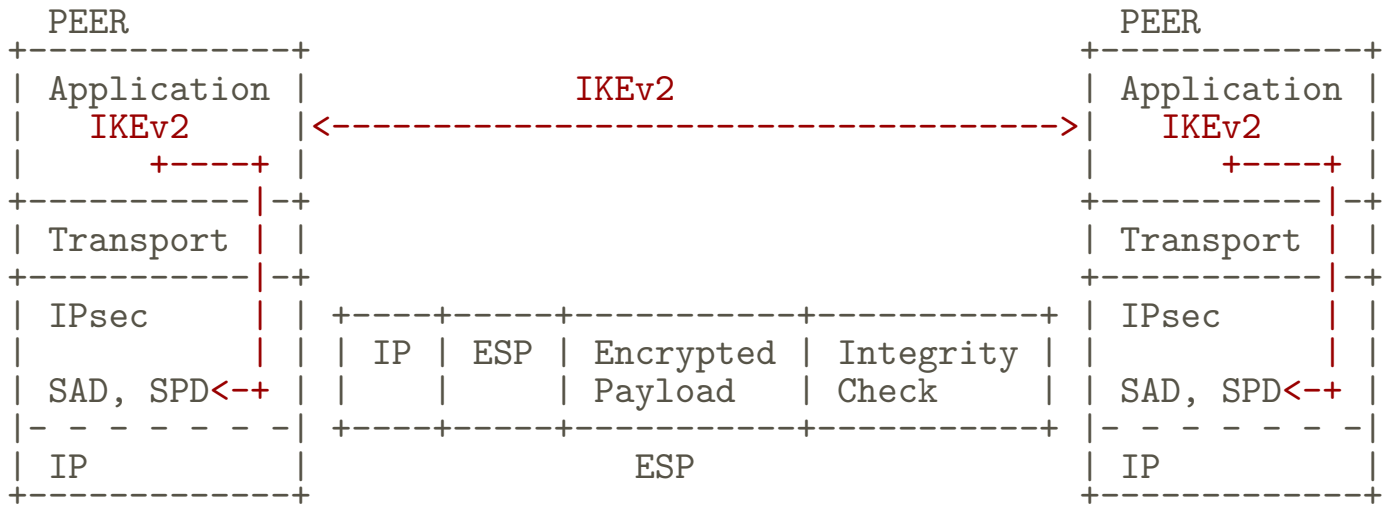

IPsec Protocol Suite

- IPsec/ESP [[RFC4303](#)] describes the format of IPsec packets
- AES-CTR [[RFC3686](#)], AES-CBC [[RFC3602](#)] AES-CCM [[RFC4309](#)] describe how to encrypt the data

IPsec Protocol Suite

- IPsec/IKEv2 [[RFC5996](#)] describes how peers agree on IPsec/ESP material

Why IPsec for IoT?

IPsec provides the following advantages:

- IPsec security is performed at the IP layer
- IPsec makes security transparent for transport and applications layer
- IPsec has no sessions and is well designed for sleeping nodes
- IPsec secures the whole device (like a firewall)

IPsec Security is usually implemented in the Kernel which makes:

- IPsec very popular for securing infrastructure
- IPsec less popular than TLS/DTLS for securing applications
- Kernel / User land should not be an issue for IoT applications

IPsec is well designed for IoT security so Diet-ESP is designed as IPsec for IoT

Diet-ESP Requirements

Identified requirements to make Diet-ESP successful for IoT are:

- Flexible Compression
- Enable low code complexity
- Easy to use / configure
- Keep the same level of security as Standard IPsec

Full list of requirements are listed in [[draft-mglt-ipsecme-diet-esp-requirements](#)]

Diet-ESP Architecture

Diet-ESP design principles:

- Keep Standard ESP as defined in [[RFC4303](#)]
- Compress / Decompress the ESP Packet

Diet-ESP Architecture

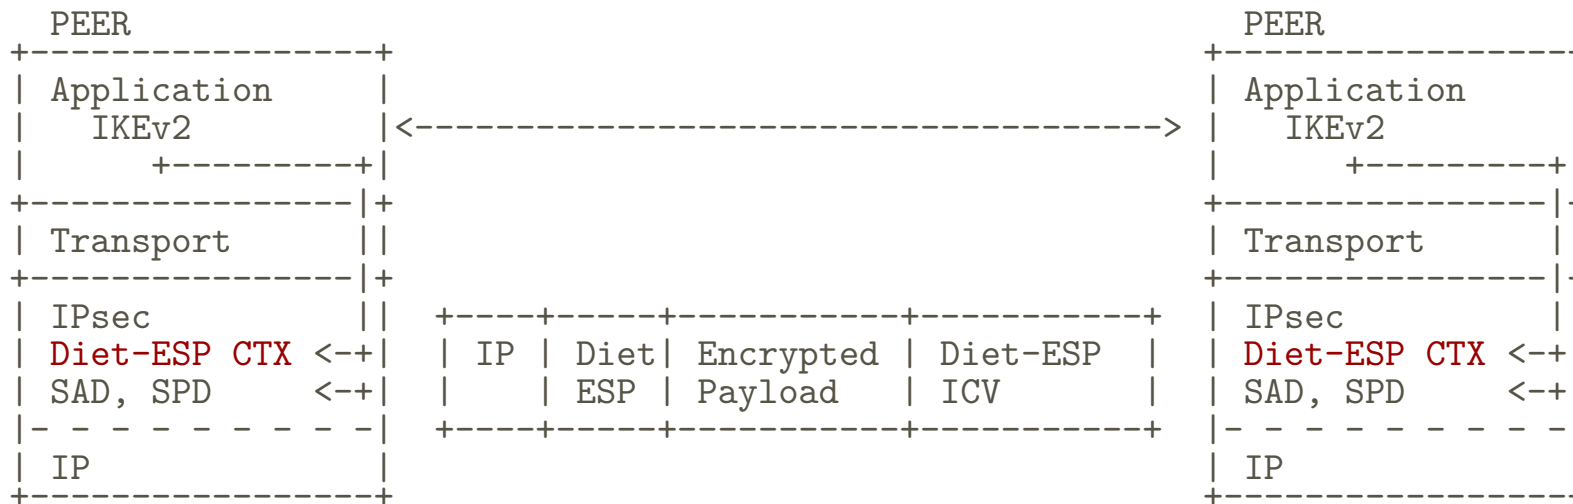

Diet-ESP Compression / Decompression

- Defined by the Diet-ESP Context
- Use IPsec information (Traffic Selectors)
- Determinist, stateless

Diet-ESP Context:

- Small – Diet-ESP Context is stored in two Bytes
- Defines hardware alignment / size ESP fields are compressed
- Security considerations of compression is documented
- Suggested default value to ease application developpers
- Can be negotiated with IKEv2

Diet-ESP Architecture

Position toward ROHC/6LowPAN

Position toward ROHC, ROHCOverIPsec, 6LowPAN, 6LowPANoverIPsec:

- Described with ROHC [[RFC3095](#)], [[RFC5225](#)] and ROHCOverIPsec [[RFC5856](#)], [[RFC5857](#)], [[RFC5858](#)] terminology
- Takes advantage of the negotiated IPsec parameters
 - ▶ Stateless compression / decompression
 - ▶ No in-band information
- Compress EVERY ESP fields
- Designed for constraint devices, not only for bandwidth optimization.
- Mostly compatible with ROHC, 6LowPAN

Compression Performance

Compression Performance

Evaluation of the IP payload for sending 1 Byte of Data:

- An example – see [EX] for more detail
- A temperature sensor sending information every hour / day

Protocol	Total Size (Bytes)	ESP	IV	UDP	ICV
ESP	40 [80]	11	8	8	12
Diet-ESP	5 [5]	0	0	0	4
6LowPAN(overIPsec)	26 [29]	4	8	1	12
ROHC(overIPsec)	24 [0]	3	8	0	12

Development Work

We have two implementations of the previous Diet-ESP version:

- Python
- Contiki

Measurements showed:

- Memory footprint: 578 Bytes
- Simulation with Cooja shows with a 20% accuracy that time and energy consumption is "linear" to the number of byte sent

Future Work:

- Update the current version to new version and new compressions
- Build a C implementation for the "Server Side"
- Define IKEv2 extention

Diet-ESP Context

- ALIGN: define the hardware supported alignment
- SPI_SIZE: Number of LSB SPI sent
- SN_SIZE: Number of LSB SN sent
- NH: defines if NH is present or not
- PAD: if the PadLength field is present or not
- Diet-ESP_ICV_SIZE: Number of LSB of the Diet-ESP_ICV
- IV_COMPRESSION: defines if the IV is compressed
- COMPRESS_ESP_PAYLOAD: defines if IPsec TS are used by compressors
- CHECKSUM_LSB: Number of LSB of the transport checksum field

Ex: ESP Packet for 1 Byte Data

Use Case: A sensor sends 1 byte of Temperature data every hour

- Data is sent over UDP Port Source, Port Destination
- IPsec Security Association is negotiated for UDP Port Source, Port Destination
- Encryption is AES-CTR [[RFC3686](#)] with an 8 Byte IV
- Integrity Check Value AES-XCBC-MAC [[RFC3566](#)] 12 Byte ICV

Ex: ESP Packet for 1 Byte Data

1 Byte Data

0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1

Ex: Diet-ESP Packet for 1 Byte Data

Definition Diet-ESP Context:

- ▶ ALIGN: 8 bit (Sensor does not require 32 bit alignment)
- ▶ SPI_SIZE: 0 (IP addresses identify the connection)
- ▶ SN_SIZE: 0 (derived from time)
- ▶ No Next Header field, No Pad Length field
- ▶ Diet-ESP_ICV_SIZE: 4 bytes instead of 12.
- IV Compression [[draft-mgmt-ipsecme-diet-esp-iv-generation](#)]
 - ▶ IV_COMPRESSION: Set IV is generated locally on both peers
- ESP Payload Compression [[draft-mgmt-ipsecme-diet-esp-payload-compression](#)]
 - ▶ COMPRESS_ESP_PAYLOAD (UDP, Ports are stored in SAD, SPD)
 - ▶ CHECKSUM_LSB: 0 (ICV provides Integrity Check)
